

# 2013 National Wagyu Sire Summary

Washington State University, Department of Animal Sciences

## Introduction

We have published Wagyu Sire summaries over the years when we have been able to obtain progeny information that can be used to make genetic comparisons among animals. The last available summary was dated 2012 and was posted on the American Wagyu Association web site. We have received carcass information on 158 progeny (74 steers and 84 heifers) from 2 additional Wagyu sires. The progeny of these sires had high marbling scores and has placed them at the high end of the marbling scale. The new data includes information for marbling, back fat and ribeye area.

Identifying Wagyu sires that excel in marbling and growth traits is important in order to engineer the type of cowherd and progeny that fit the market and overall goals of the modern beef cattle industry faster. Wagyu cattle appear to be able to attain more marbling and produce lighter calves at birth than other beef breeds in the United States. However, not all animals have the same genetic ability to produce marbling and desirable growth traits. Therefore, in order to produce slaughter animals with certain live and carcass specifications, only sires with higher genetic potential for those traits should be used.

EPD's are the best estimates that we have of an animal's genetic potential. These estimates take into consideration all information that is available for an animal. The attached tables give EPD's for several carcass and growth traits for a number of Wagyu sires in the United States. All of the information in this summary is based on measurements from half blood Wagyu animals. These animals were raised in contemporary groups (CG's). A contemporary group consists of animals raised under the same management conditions. The number of progeny and number of contemporary groups for each sire are listed in the summary tables for each trait.

EPD's are not true values, but predictions and we expect them to change with new information. The reliability of an EPD is indicated by its accuracy (ACC), which is reported as a decimal number ranging from 0 to 1. Accuracy values closer to one indicate that the change in the EPD will be small. When the accuracy is closer to zero, a larger change is expected. Accuracy increases as the number of progeny and contemporary groups increases.

The total number of animals with marbling data was 2,897, with external fat data was 744 and 691 for ribeye area.

These EPD's were computed using a system called abtk at the Center for Genetic Evaluation of Livestock (CGEL) in the Animal Science Department at Colorado State University. Thank you to Dr. Mark Enns the director of CGEL.
